Who pays for job training?

Parantap Basu Durham University Anurag Banerjee Durham University

Abstract

A puzzling feature of the UK labour market is that there is not enough investment in job training (either by workers or by firms) while there is a high skill premium. We model this as a two sector (skilled and unskilled) economy with a non-cooperative training game between vacant skilled firms and unemployed unskilled workers. A vacant skilled firm has an incentive to train an unskilled worker because of the chance of a better match with a skilled worker. On the other hand, an unskilled worker has an incentive to train because it could increase his lifetime earning. Using a social planning problem as a baseline, the paper demonstrates that while it is socially optimal to invest in job training, the private sector may fail to internalize these benefits in a wide range of economies. Calibrating the model for the UK economy, we compute the welfare gain due to the institution of job training in various environments. The welfare gain from a training programme is highest if workers instead of firms bear the cost of training. The model also predicts that the income inequality could rise when a job training programme is in place.

The paper should be assigned to the session organized by Itzhak Zilcha. **Submitted:** January 31, 2011.

Who pays for job training?

Abstract

A puzzling feature of the UK labour market is that there is not enough investment in job training (either by workers or by firms) while there is a high skill premium. We model this as a two sector (skilled and unskilled) economy with a non-cooperative training game between vacant skilled firms and unemployed unskilled workers. A vacant skilled firm has an incentive to train an unskilled worker because of the chance of a better match with a skilled worker. On the other hand, an unskilled worker has an incentive to train because it could increase his lifetime earning. Using a social planning problem as a baseline, the paper demonstrates that while it is socially optimal to invest in job training, the private sector may fail to internalize these benefits in a wide range of economies. Calibrating the model for the UK economy, we compute the welfare gain due to the institution of job training in various environments. The welfare gain from a training programme is highest if workers instead of firms bear the cost of training. The model also predicts that the income inequality could rise when a job training programme is in place.

1 Introduction

A striking feature of the UK labour market is the simultaneous presence of a staggering skill premium between high and low skilled jobs and underinvestment in job training. Since 1986, more jobs require advanced skill. According to Felstead et al. (2002), a substantial skill premium exists at the graduate level (57% for women and 38% for men) compared with jobs which require no qualification. Felstead et al. (2002) also document that there is a shortage of high-skilled workers (level 4) while there is an excess supply of workers with intermediate skills and low skills (levels 3 and 2).¹On the other hand, there is little evidence of worker participation in training. Schömann and Siarov (2005) provide evidence of low worker participation of training in the Euroepan union. Although there was a steady increase in training participation (about 2.5%) over the period 1995-2003, it significantly falls short of the Lisbon target of 15%. They also observe a remarkable disparity in training participation of low and high skilled workers.

These findings are puzzling. If there is such a high skill premium, why is this not exploited by the workers and firms? If a large number of skilled, well paid jobs are vacant, one expects that workers would invest in job training and reap the benefits. Instead, workers are content to acquire lesser intermediate qualifications in the labour market. Low skilled workers hardly undertake any investment in training to upgrade their skills. There is also little evidence that skilled firms train unskilled workers while skill shortages are persistent.² The bottom-line is that a high skill premium coexists with a glaring underinvestment in training.

The focus of our paper is to understand this issue in a strategic framework. The job training decision is modelled as a dynamic game between workers and firms in an environment where there are search frictions of finding the right match of vacancy with skill. In our model, only two active agents have the potential to invest in training. These are, namely a skilled firm which has a job vacancy and an unskilled worker who does not presently have a job. These economic agents cannot simultaneously invest in training and continue to work/produce because of the indivisibility of time.

¹The following quotation from Felstead et al. (2002) aptly summararizes this supply-demand imbalance: "...there are 6.4 million people qualified to the equivalent of NVQ level 3 in the workforce, but only 4 million jobs that demand this level of highest qualification. There are a further 5.3 million people qualified at level 2, but only 3.9 million jobs that require a highest qualification at this lower level."

 $^{^{2}}$ Haskel and Martin (2001) document that the skill shortage is greater for firms employing advanced technology.

There are several passive agents such as skilled and unskilled employed workers and skilled engaged firms. However, they experience the externality from a job training programme because it impacts the skilled-unskilled wage differential.

Both these active agents have incentive as well as disincentive to invest in training. A vacant skilled firm has an incentive to recruit an unskilled unemployed worker and train him because in this way it can increase its chance of being engaged and avoid the cost of keeping a position vacant until it finds a right match. An unemployed unskilled worker has an incentive to engage in job training because by doing so it can increase the likelihood of finding a skilled job and improve his life time earning profile. The disincentive for training for both these firms and workers arises for strategic reasons. Given a high training cost, an unskilled unemployed worker may rather wait for a match with a skilled vacant firm who will select him for a job training programme. A vacant skilled firm, on the other hand, may find it costly to train a worker vis-a-vis keeping the position vacant. It may thus wait until it finds a skilled worker. This strategic interdependence may give rise to an inefficient Cournot-Nash equilibrium where none may invest in training for a range of training costs.

The equilibrium where neither party invests in job training programme is deemed to be privately optimal but not socially optimal. This discrepancy between private and social values arises simply because of an externality. Workers or firms in isolation fail to internalize the social benefits of upgrading skills through a job training programme. If such a discrepancy between social and private values arises, we call it a "coordination failure" in the action of firms and workers.

We formally characterize this coordination failure by setting up a fictitious social planning problem where the benevolent social planner internalizes the search frictions, costs of vacancy and the value of leisure. The planner then dictates whether the firms or households should invest in job training and if so how much training cost each party should bear. Given this social planning model as the baseline, we ask whether there is enough incentive for the private sector to invest in such a training programme.

Based on the UK and OECD studies, we calibrate the model specific parameters and compute welfare gain due to the institution of a job training in various environments. The welfare gain from job training programme is highest in a command economy where the social planner internalizes all the private costs and benefits of training. In a decentralized economy, magnitude of this welfare gain depends on who adopts training. The overall welfare gain is higher in a private economy if instead of firms, unskilled workers bear the cost of training. For our calibrated economy the overall welfare gain from job training can range from 7 to 10%. The welfare gain could be higher if skilled firms are subsidized by the government or the unemployment benefit is reduced for the workers making leisure expensive to them. We also find that the income inequality could rise when a job training programme is in place. This happens primarily because a job training programme increases the skilled unemployment in our model because number of skilled firms do not change but number of skilled workers increase.

Our model contributes to a long standing literature on financing of training that started from the seminal work of Becker (1965). Becker pointed out that in a competitive labour market environment firms have no incentive to provide general training to workers as this training is fully transferrable to other firms. Accemoglu and Pischke (1999) and Stevens (1994) argue that when firms have labour market power, they may reap some benefits from investing in general training. Since skilled workers face worse outside options, wage structure becomes compressed.

In our model, if firms invest in training, they are worse off and workers benefit. If workers invest in training both parties are better off. When vacant firms invest in training, the trained worker enjoys a bargaining advantage to strike a higher wage because the firm has already borne the sunk cost of training him. This raises the wage cost and consequently lowers the profit of all skilled firms in the economy. This explains why all skilled firms are worse off when a vacant skilled firm invests in training. On the other hand, if an unskilled worker invests in training, he does not gain any such bargaining strength because he just acquires the same level of skill as a born skilled worker. Our calibration experiment with UK data suggests that the skilled firms can lose about 23% of welfare when firms invest in training while they will gain by 11% if workers invest in training. The overall gain in welfare for all parties is 4% higher when instead of firms, workers bear the cost of training.

The paper is organized as follows. In the following section, we lay out the environment and set up a model of strategic job training. Section 3 describes the social planning model. Section 4 reports the quantitative analysis of the model. Section 5 concludes.

2 The Model

Two types of technologies are available: high-skill (suffixed as s) and low-skill (suffixed as u). Each of these technologies could produce p^s and p^u units of output if it is operated by a skilled and unskilled worker respectively. The skilled sector has a higher productivity which means $p^s > p^u$. There are continuum of such skilled and unskilled workers and firms in a unit interval. Initially there are μ_0^{sw} proportion of skilled workers and μ_0^{sf} firms. There is also an initial distribution of vacant skilled and unskilled firms denoted as v_{00}^s and v_{00}^u respectively and an initial distribution of unemployed skilled and unskilled workers denoted as u_{00}^s and u_{00}^u respectively.

There are two types of provisions for job training in the economy: (i) unskilled unemployed worker undertakes self-training by joining a skill center, and (ii) vacant skilled firm imparts job training to an unskilled worker. In both cases, an unskilled worker turns skilled in the next period. The only decision problem for either the unskilled unemployed worker or the skilled vacant firm is whether to invest resources in job training.³ Such a decision is represented by an indicator function ξ_t^w, ξ_t^f respectively taking on values 0 or 1 for no training and training for worker and firm respectively.

Vacant firms and unemployed workers randomly match. At each date, u_t^i proportion of unemployed *i*-type workers meet v_t^j (j = s, u) proportion of vacant firms. Let λ^{ij} be the probability that such a match consummates. The matching function is thus given by: ⁴

$$M_t^{ij} = \lambda^{ij} u_t^i v_t^j \tag{2.1}$$

Based on the technology and the provisions of job training, three types of matching are conceivable: (i) a high skilled worker successfully matches a vacant high skilled firm, and produces output p^s , (ii) a low skilled worker successfully matches a vacant low skilled firm and produces p^u , (iii) a low skilled worker successfully matches a vacant high skilled firm and this vacant firm decides to train this worker by incurring a training cost. Each period a fixed fraction σ^i of existing matches in the skilled and unskilled sector die due to exogenous retirement or layoffs.

Let μ_t^{if} and μ_t^{iw} be the number of the i-th type firms and workers respectively.

$$\Delta u_t^s = \sigma^s(\mu_t^{sw} - u_t^s) - \lambda^{ss} u_t^s v_t^s + \xi_t^w u_t^w v_t^s (1 - \lambda^{ss})$$

$$\tag{2.2}$$

 $^{^{3}}$ Since the focus of this paper is on job training, for simplicity we reule out the possibility of technology upgrade by unskilled firms to turn skilled.

⁴This matching function is known in the literature as a quadratic matching function following Diamond and Maskin (1979). Such a matching function can be motivated by the illustrative example borrowed from Mortensen and Pissarides (1998) that both matched and unmatched firms and households have a telephone book of all matched and unmatched agents on the other end of the market. A quadratic matching function may give rise to multiple equilibria. In our context, we break such multiplicity by invoking an initial distribution of skilled and unskilled workers and firms.

$$\Delta u_t^u = \sigma^u (\mu_t^{uw} - u_t^u) - \lambda^{uu} u_t^u v_t^u - \xi_t^w u_t^u - \xi_t^f \lambda^{us} u_t^u v_t^s$$
(2.3)

$$\Delta v_t^s = \sigma^s (\mu_t^{sf} - v_t^s) - \lambda^{ss} u_t^s v_t^s - \xi_t^f \lambda^{us} u_t^u v_t^s$$
(2.4)

$$\Delta v_t^u = \sigma^u (\mu_t^{uf} - v_t^u) - \lambda^{uu} u_t^u v_t^u$$
(2.5)

$$\Delta \mu_t^{sw} = \xi_t^w u_t^u + \xi_t^f \lambda^{us} u_t^u v_t^s \tag{2.6}$$

$$\Delta \mu_t^{sf} = 0 \tag{2.7}$$

A few clarification of the terms in the transition equations are in order. The transition equation (2.2) shows that the number of skilled unemployed increases when job separations occur (first term) or unemployed unskilled worker meets a vacant skilled firm after completing self-training in a skill center but the match does not consummate (third term). On the other hand, the number of high skilled unemployed decreases if a vacant skilled firm meets a high skilled worker and the match is successful (second term). Similar explanation applies to the first two terms of (2.3). The third term of (2.3) reflects the fact that the number of unskilled unemployed workers decreases when an unskilled worker joins the skill center and thus withdraws from the pool of unskilled unemployed and joins the pool of skilled unemployed. The fourth term means that when an unskilled worker meets a skilled vacant firm and the match consummates the number of low skilled unemployed workers decreases.

The transition equation (2.4) for the vacant skilled firms shows that the number of vacant firms increases when a job separation occurs (first term). The number of vacant firms decreases when a vacant skilled firm successfully matches with an unemployed skilled worker or when a vacant skilled firm successfully matches with a low skilled worker (third term). The transition equation (2.5) for vacant unskilled firms is self-evident.

The transition equation for the skilled workers (2.6) means that more skilled workers evolve as more skilled firms invest in job training (the first term) or more unskilled workers invest in job training (the second term). The transition equation (2.7) reflects that the number of high skilled firms is constant over time.

We focus on the steady state analysis only. There are four possible steady states for this system: (i) firms invest in training while workers do not, $\xi_t^f = 1, \xi_t^w = 0$,(ii) firms do not invest in training but workers do, $\xi_t^f = 0, \xi_t^w = 1$, (iii) both invest in training, $\xi_t^f = 1, \xi_t^w = 1$, (iv) none invest in training, $\xi_t^f = 0, \xi_t^w = 0$. Define the set of steady states in training as $\Pi = \{10, 01, 11, 00\}$ where the first element of each tuple is the training state of the firm, ξ_t^f and the second is the same of the worker, ξ_t^w . Let π stand for an element of the set Π .

In the following lemma, we prove that if at least one party invests in job training, all unskilled workers turn skilled and all unskilled jobs remain vacant.

Lemma 1 The states where at least one of the agents invest in education (meaning $\pi \neq 00$) the stable steady state solutions of the transition equations are given by

1. $u_{\pi}^{u} = 0, v_{\pi}^{u} = \mu_{0}^{uf},$ 2. $\mu_{\pi}^{sw} = 1, \mu_{\pi}^{uw} = 0,$ 3. $\mu_{\pi}^{sf} = \mu_{0}^{sf} = 1 - \mu_{\pi}^{uf},$ 4. $u_{\pi}^{s} = \overline{u}^{s} \equiv \frac{1}{2} \left(\left[\overline{\delta}^{s} - \eta^{ss} \right] + \sqrt{\left[\overline{\delta}^{s} - \eta^{ss} \right]^{2} + 4\eta^{ss}} \right)$ and 5. $v_{\pi}^{s} = \overline{v}^{s} \equiv \overline{u}^{s} - \overline{\delta}^{s}$

where $\eta^{ss} = \frac{\sigma^s}{\lambda^{ss}}$ and $\overline{\delta}^s = 1 - \mu_0^{sf}$.

Proof of Lemma. : Appendix 1. ■

If at least one person invests in training, unskilled workers disappear in the economy. This means that the unemployment rate for unskilled workers goes to zero and all unskilled firms remain vacant. This explains results (1), (2) and (3) of Lemma 1. On the other hand, there is still some natural rate of unemployment and vacancy in the skilled sector due to matching frictions which are characterized in results (4) and (5). Result (5) states that after training, the number of active skilled firms $\left(\mu_0^{sf} - \overline{v}^s\right)$ exactly balances the number employed skilled workers $(1 - \overline{u}^s)$.

When nobody invests in training, the number of high skilled and low skilled workers do not change from its initial level. The following lemma formalizes it.

Lemma 2 : The state where no-one invests (meaning $\pi = 00$) the stable steady state solutions of the transition equations is given by

$$\mu^{iw} = \mu_0^{iw}; \mu^{iw} = \mu_0^{iw} \tag{2.8}$$

$$u_{00}^{i} = \frac{1}{2} \left(\left[\delta_{0}^{i} - \eta^{ii} \right] + \sqrt{\left[\delta_{0}^{i} - \eta^{ii} \right]^{2} + 4\eta^{ii} \mu_{0}^{iw}} \right)$$
(2.9)

$$v_{00}^i = u_{00}^i - \delta_0^i \tag{2.10}$$

where $\delta_0^i = \left(\mu_0^{iw} - \mu_0^{if}\right)$ and $\eta^{ii} = \frac{\sigma^i}{\lambda^{ii}}, i = u, s.$

Proof of Lemma:. Appendix 1.

Lemmas (1) and (2), enable us to reduce the number of states to two, namely: (i) state of no training and (ii) state of training. Define

$$\overline{\xi} \equiv 1 - (1 - \xi^f) (1 - \xi^w) = 1 \quad \text{if at least one party invests in training} \\ = 0 \quad \text{otherwise}$$

$$(2.11)$$

Then the vacancy and unemployment rates in each sector can be rewritten in a compact form as:

$$v_{\pi}^{i} = \left(1 - \overline{\xi}\right) v_{00}^{i} + \overline{\xi} \overline{v}^{i} , i = u, s$$

$$(2.12)$$

$$u_{\pi}^{i} = \left(1 - \overline{\xi}\right) u_{00}^{i} + \overline{\xi} \overline{u}^{i}, \ i = u, s$$

$$(2.13)$$

When at least one party invests in training, it also increases unemployment rate in the skilled sector because the number of skilled firms do not change while the number of skilled workers increase. Since this results in an increase in the matching probability of the skilled firm, we shall see later that this gives rise to an incentive for the skilled firms to invest in training.

Corollary 1 : The unemployment is higher in the skilled sector in states where at least one of the agents invests in training, that is

$$\overline{u}^s \ge u_{00}^s.$$

Proof. Appendix 1.

The unemployment and the vacancy rates in the no-training state are determined by the initial shortage of workers in each sector characterized by δ_0^i and also notice that $\delta_0^s = -\delta_0^u$. Hereafter we shall define δ_0^s as the initial skill gap in the economy. Also noting that under this setup the distribution of skilled and unskilled firms do not change, therefore initial skill gap δ_0^s is smaller than the skill gap after training $\overline{\delta}^s$ (i.e. $\overline{\delta}^s > \delta_0^s$).

3 Strategic Job Training

We now turn our attention to a decentralized environment where the job training decisions are made in a noncooperative, strategic environment. Let sc be the cost for training a worker. Let b be a common leisure value of any unemployed worker of any type, c be a common cost of keeping a production unit vacant and ω^i be the wage prevailing in the *i*-th sector. Unskilled workers while deciding to incur training costs take into account that even if they do not incur this cost, there is a chance of being hired by a skilled firm and getting trained subsequently. A skilled firm while contemplating to train an unskilled worker internalizes the fact that the same worker may leave the firm after training. The job training thus appears as an equilibrium outcome of a dynamic game between workers and firms in a search environment.

There are eight types of agents in our economy: (i) unskilled employed and unemployed workers, (ii) skilled employed and unemployed workers, (iii) vacant skilled and unskilled firms, (iv) active skilled and unskilled firms. Define the value functions of these eight types as: E^u , U^u , E^s , U^s , V^s , V^u , J^s , J^u respectively. Among these eight types, only unskilled unemployed workers and vacant skilled firms can invest in job training and are thus deemed as *active players* in training decisions. The remaining six agents are passive in the sense that they do not involve in job training. It is assumed that all engaged skilled and employed unskilled workers use a fixed amount of time for production. This time is indivisible in the sense that it cannot be divided between production and investment in training. This explains why all engaged skilled firms and unskilled workers cannot invest in training. Since we rule out the possibility of a technological upgrade by an engaged unskilled firm, it is not worthwhile for such a firm to invest in job training. Nevertheless, these passive agents still experience externality from the training decisions of these passive agents thus depend on the Nash equilibrium arising from the strategic training decisions of unskilled unemployed worker and vacant skilled firms. To see this clearly, let us first spell out U^u and V^s .

3.1 Value Functions of the Active Players

The only initial state of interest here is the state of no training because otherwise there are no unskilled workers in the economy by virtue of Lemma 1. An unskilled unemployed collects unemployment benefit at present and has two choices: train himself or not to train himself. If he goes for selftraining, there are two prospects: (i) the prospect of being matched with a vacant skilled firm with probability $\lambda^{ss} v_{\pi}^{u}$ or (ii) the prospect of no such match with either skilled or unskilled firm. If he does not go for self-training, three possibilities lend themselves: (a) he can be matched with either a vacant unskilled firm with probability $\lambda^{uu} v_{\pi}^{u}$, (b) he could remain unemployed with a prospect of being matched with a vacant skilled firm who may impart training to him with a probability $\lambda^{us} v_{\pi}^{s}$, (c) he may simply remain unemployed without any match whatsoever. If he indeed matches with a vacant skilled firm who imparts training to him, during the training period he does not produce anything or does not receive any wages. During this training state, his status is thus deemed to be unskilled unemployed.

The value function of an unskilled worker is thus given by:

$$U^{u}\left(\xi^{f},\xi^{w*}\right) = b - \xi^{w*}sc + \xi^{w*}\beta \left[\lambda^{ss}v_{\pi}^{s}E^{s} + (1 - \lambda^{ss}v_{\pi}^{s})U^{s}\right] + (1 - \xi^{w*})\beta \left[\begin{array}{c} \lambda^{uu}v_{\pi}^{u}E^{u} + \lambda^{us}v_{\pi}^{s}U^{u}(\left(\xi^{f},\xi^{w*}\right) \\ + (1 - \lambda^{uu}v_{\pi}^{u} - \lambda^{us}v_{\pi}^{s})U^{u}\left(\xi^{f},\xi^{w*}\right) \end{array} \right]$$
(3.14)

where $\xi^{w*} = \arg \max_{\xi^w} U^u \left(\xi^f, \xi^w\right)$.

Next consider the formulation of V^s . A vacant skilled firm currently incurs the sunk cost c of keeping its unit vacant and also a possible training cost depending on whether it decides to train an unskilled worker. If it decides to train, the same trained worker turns skilled and the relationship can endure with a probability $\lambda^{ss} u_{\pi}^s$ which means that the vacant skilled firm turns active with the trained skilled worker. Notice that by corollary $1 \lambda^{ss} u_{00}^s < \lambda^{ss} \overline{u}^s$ i.e. the probability of matching increases with training. If the matching does not work out, the vacant skilled firm remains inactive with complement probability $(1 - \lambda^{ss} u_{\pi}^s)$. On the other hand, if the skilled vacant firm does not spend on training, there is still a chance of a match with a skilled worker with probability $\lambda^{ss} u_{\pi}^s$. The value function of the vacant skilled firm is thus given by:

$$V^{s}\left(\xi^{f*},\xi^{w}\right) = -c - \xi^{f*}sc + \xi^{f*}\beta \left[\lambda^{ss}u_{\pi}^{s}J^{s} + (1 - \lambda^{ss}u_{\pi}^{s})V^{s}\left(\xi^{f*},\xi^{w}\right)\right] + \left(1 - \xi^{f*}\right)\beta \left[\lambda^{ss}u_{\pi}^{s}J^{s} + (1 - \lambda^{ss}u_{\pi}^{s})V^{s}\left(\xi^{f*},\xi^{w}\right)\right] = -c - \xi^{f*}sc + \beta \left[\lambda^{ss}u_{\pi}^{s}J^{s} + (1 - \lambda^{ss}u_{\pi}^{s})V^{s}\left(\xi^{f*},\xi^{w}\right)\right]$$
(3.15)

where $\xi^{f*} = \arg \max_{\xi^f} V^s \left(\xi^f, \xi^w\right)$. It is important to observe that the skilled vacancy rate v_{π}^s and the unemployment rate u_{π}^s depend on the state of training via (2.12) and (2.13).

3.2 Value Functions of the Passive Agents

We next formulate the value functions of the remaining six types of agents who are deemed as passive since they do not undertake any training decisions. However, each of their values depends on the training decisions ξ^f and ξ^w of skilled vacant firms and unskilled unemployed workers through the vacancy and unemployment rate v^i_{π} and u^i_{π} (in (2.12) and (2.13)) and wages which will be specified in the next section. As all these passive agents do not involve in training decision, we do not hereafter write the values of these agents as functions of ξ^f and ξ^w .

A skilled employed worker can earn a wage ω^s today and faces two scenarios: (i) stay employed in the next period with a probability $(1 - \sigma^s)$ or (ii) join the pool of skilled unemployed with probability σ^s . A skilled unemployed worker collects unemployment benefits, b today and faces the prospect of being matched with a vacant skilled firm with probability $\lambda^{ss}v_{00}^s$ when there is no investment in training and with probability $\lambda^{ss}\overline{v}^s$ when there is investment in training.⁵ Thus, the value functions of skilled employed and unemployed are given by:

$$E^{s} = \omega^{s} + \beta \left[\sigma^{s} U^{s} + (1 - \sigma^{s}) E^{s} \right]$$

$$(3.16)$$

$$U^{s} = b + \beta \left[\lambda^{ss} v_{\pi}^{s} E^{s} + (1 - \lambda^{ss} v_{\pi}^{s}) U^{s} \right]$$
(3.17)

Likewise an unskilled employed worker has the following value function:

$$E^{u} = \omega^{u} + \beta \left[\sigma^{u} U^{u} + (1 - \sigma^{u}) E^{u} \right]$$
(3.18)

An active unskilled firm produces p^u and after paying wage ω^u to the worker and faces two prospects next period: (i) stay active with a probability $(1-\sigma^u)$ or (ii) join the pool of vacant unskilled firms with probability σ^u . An inactive (vacant) unskilled firm incurs the vacancy cost c and faces the prospect of being matched with an unemployed unskilled worker with a probability $\lambda^{uu} u^u_{\pi}$ or stay vacant with a

 $^{{}^{5}}$ It is assumed that skilled unemployed worker does not search for a job in the unskilled sector.

probability $(1 - \lambda^{uu} u^u_{\pi})$. The value functions for the unskilled firms are thus given by:

$$J^{u} = p^{u} - \omega^{u} + \beta \left[\sigma^{u} V^{u} + (1 - \sigma^{u}) J^{u} \right]$$
(3.19)

$$V^{u} = -c + \beta \left[\lambda^{uu} u^{u}_{\pi} J^{u} + (1 - \lambda^{uu} u^{u}_{\pi}) V^{u} \right]$$
(3.20)

Likewise an active skilled firm has a value function:

$$J^s = p^s - \omega^s + \beta[(1 - \sigma^s)J^s + \sigma^s V^s]$$
(3.21)

Wage Determination

The wage in each sector is determined by a Nash bargaining:

$$\omega^{s}\left(\xi^{f*},\xi^{w*}\right) = \arg\max_{\omega^{s}}\left(E^{s}-U^{s}\right)^{\theta}\left(J^{s}-V^{s}\left(\xi^{f*},\xi^{w*}\right)\right)^{1-\theta} \text{ and } (3.22)$$

$$\omega^u \left(\xi^{f*}, \xi^{w*}\right) = \arg \max_{\omega^u} \left(E^u - U^u \left(\xi^{f*}, \xi^{w*}\right)\right)^\theta (J^u - V^u)^{1-\theta}$$
(3.23)

respectively where θ is a non-negative fraction representing the bargaining strength of the worker and (ξ^{f*}, ξ^{w*}) are equilibrium strategies. The Nash bargaining wage is basically the weighted average of the flow excess return of the firm from employing a worker vis-a-vis keeping the position vacant and the flow excess return of the worker taking a job vis-a-vis staying unemployed. In addition, the wage also depends on the state of training. We have an important result.

Lemma 3

$$\omega^{s}(1,0) > \omega^{s}(0,1) \tag{3.24}$$

Proof. Appendix.

In other words, when firms bear the cost of training, wages in the skilled sector is higher than a scenario when workers bear the cost. A vacant skilled firm in our model becomes engaged by virtue of this newly trained woker and thus has to pay a higher wage to keep this worker. On the other hand, when an unskilled unemployed bears the cost of training, he just acquires the same level of skill as a born skilled worker. This means that he cannot strike a higher wage bargain and shift the cost of training to the employer.

Characerization of Equilibrium

We now define formally a Nash equilibrium for our economy which reflects the interdependence of workers and firms through the training decisions of the active players.

Definition: Given the initial state of no training and a training cost of sc, a Nash equilibrium in training satisfies the following two conditions:

(i) An unskilled unemployed worker chooses the training decision ξ^w optimally taking the training decision (ξ^f) of the vacant skilled firm as given. In other words, $U^u(\xi^{f*}, \xi^{w*}) \ge U^u(\xi^{f*}, \xi^w)$

(ii) A vacant skilled firm chooses the training decision ξ^f optimally taking the training decision (ξ^w) of the vacant skilled firm as given. In other words, $V^s\left(\xi^{f*},\xi^{w*}\right) \geq V^s\left(\xi^f,\xi^{w*}\right)$.

(iii) Given the training decisions of unskilled workers and vacant skilled firms, other workers behave optimally and solve (3.16), (3.17), (3.18).

(iv) Given the training decisions of unskilled workers and vacant skilled firms, other firms behave optimally and solve (3.19), (3.20) and (3.21).

(v) Given the optimal training decisions of workers and firms, wages are determined by Nash bargaining as in (??).

Depending on the schooling cost, various equilibria are possible where either the firm or worker may or may not choose to invest in training. We are particularly interested in a Nash equilibrium where none invests in training while it is socially optimal that at least someone invests in training. Such a scenario is deemed to be a coordination failure among agents because private agents do not internalize certain social benefits of training. To understand the nature of this coordination failure, we proceed in two steps. First, we characterize the range of schooling costs for which there is a Nash equilibrium in no training. Second, we set up a social planning problem where the fictitious social planner internalizes all the benefits and costs of training and show the conditions under which it is socially optimal to invest in training but not privately optimal.

3.3 Coordination Failure in Training: No Training Equilibrium

Given the initial state of no training and a training cost of sc, a Nash equilibrium where nobody invests in training satisfies the following two conditions:

1. Given that firms do not bear training cost, workers will not pay if

$$U^{u}(0,1) < U^{u}(0,0).$$
(3.25)

2. Given that workers do not pay, a vacant skilled firm will not incur the training cost if

$$V^{s}(1,0) < V^{s}(0,0).$$
 (3.26)

Since $U^u(0,1)$ and $V^s(1,0)$ are monotonically decreasing in sc, there exists a threshold training cost sc_w^{n*} for which (3.25) holds as equality.⁶ The worker does not pay for training when the firm does not pay if

$$sc > sc_w^{n*} \tag{3.27}$$

Likewise, there exists a threshold schooling cost sc_f^{n*} for which (3.26) holds as equality. Given that the worker does not pay, the firm does not pay for training if

$$sc > sc_f^{n*} \tag{3.28}$$

The appendix provides an algebraic derivation of these two thresholds.

Based on the above analysis we have the following proposition.

Proposition 2 If the training cost per pupil is such that

$$sc > \max(sc_w^{n*}, sc_f^{n*}) = sc^{n*}(say)$$
 (3.29)

neither vacant skilled firm nor the unemployed unskilled worker finds it worthwhile investing in training.

 $[\]overline{{}^{6}\text{From (A.21) it is obvious } \frac{\partial U^{u}(0,1)}{\partial sc} = -1} \text{ and from (A.20) } \frac{\partial V^{s}(1,0)}{\partial sc} = -\frac{1}{1-\beta} \left(1 - \frac{\theta \beta \lambda^{ss} \overline{u}^{s}}{1-\beta(1-\sigma^{u}-\lambda^{ss} \overline{u}^{s})}\right) < 0, \text{ which establishes the monotonicity of } U^{u}(0,1) \text{ and } V^{s}(1,0).$

4 Socially Optimal Training

We next turn to a social planning problem where the social planner internalizes the costs and benfits of training. The planner mandates whether a firm or a worker should spend on job training while internalizing the benefits and costs of keeping workers unemployed and positions vacant. We focus on steady states only. The social planner takes the steady state configurations of the relevant state variables, $u_t^s, u_t^u, v_t^s, v_t^u, \mu_t^{sw}, \mu_t^{sf}$ as given. Based on the previous lemmas, the steady states of the economy are entirely dependent on the state of training, π .⁷ Since the steady state values of these state variables are also functions of λ^{ij} and σ^i , the social planner internalizes the search frictions while reaching a decision about job training.

There are four possible states of training for $\pi \in \Pi$. The only relevant initial steady state is when there is no past investment in training (meaning $\pi = 00$) because we know from Lemma 1 that otherwise everybody is trained to start with, thus making job training redundant. Starting from this initial state, planner can mandate four possible actions: (i) no change meaning $\xi^f = 0$, and $\xi^w = 0$, (ii) ask only firms to invest in training, $\xi^f = 1$, and $\xi^w = 0$, (iii) ask only workers to invest in training, $\xi^f = 0$, and $\xi^w = 1$ and (iv) ask both to invest in training, $\xi^f = 1$, and $\xi^w = 1$. The planner chooses the action that gives the best societal value.

Define r_{π} as the steady state proceeds to the social planner at the state π . This can be written as:

$$r_{\pi} = \sum_{i=s,u} \left[p^{i} (\mu_{\pi}^{iw} - u_{\pi}^{i}) + b u_{\pi}^{i} - c v_{\pi}^{i} \right].$$
(4.30)

In other words, the steady state proceeds to the planner is the sum total of outputs from skilled and unskilled sectors plus the total leisure benefits to the skilled and unskilled workers minus the total vacancy costs of skilled and unskilled units. Note that the social planner internalizes the utility value of leisure and vacancy costs in the proceeds, r_{π} . In contrast, in a decentralized Nash economy, a firm does not internalize the leisure value of workers and neither does the worker internalize the vacancy cost of firms.

⁷In principle, the entire history of training should comprise the current state facing the planner. However, given the absorbing nature of the state (meaning when either the worker or the firm invests in training, an unskilled worker or firm turns permanently skilled next period), the current state is thus summarised only by the current state of job training.

We have the following lemma.

Lemma 4 Define $\overline{r} \equiv p^s(1 - \overline{u}^s) + b\overline{u}^s - c(\overline{v}^s + \overline{v}^u)$, then $r_{01} = r_{10} = r_{11} = \overline{r}$.

Proof. Replacing the values of μ_{π}^{iw} , u_{π}^{i} , u_{π}^{i} , v_{π}^{i} , in (4.30) for i = u, s and $\pi \neq 00$, from lemma (1) gives the result.

In other words, the social planner is indifferent who invests in training. If at least one party invests in training, the steady state social proceeds from this is given by \bar{r} which is the skilled sector output plus benefits of skilled unemployed people minus the vacancy costs.

This simplifies the social planner's problem enormously. Starting from a no training state, if the social planner decides not to mandate any training programme, the social value is given by $\frac{r_{00}}{1-\beta}$ where

$$r_{00} = \sum_{i=u,s} \left[p^{i} (\mu_{0}^{iw} - u_{00}^{i}) + (b - c) u_{00}^{i} \right]$$

If the planner mandates a training programme, the society incurs a training cost, $sc.u_{00}$ today but in the next period it lands in a state where everybody is skilled and the social value is $\frac{\bar{r}}{1-\beta}$

The planner thus initiates a change from no training to positive training if

$$\frac{r_{00}}{1-\beta} \le r_{00} - sc.u_{00}^u + \beta \frac{\overline{r}}{1-\beta}$$
(4.31)

which means that

$$sc.u_{00}^u \le \frac{\beta}{1-\beta} [\overline{r} - r_{00}] \tag{4.32}$$

The planner finds it worthwhile mandating job training if the training cost (left hand side of (4.32)) exceeds the annuity value of the proceeds differential when the planner initiates a change from no training to positive training (the right hand side of (4.32)).

Based on (4.32) it immediately follows that the social planner mandates investment in training if the schooling cost (sc) is below a certain threshold given by:

$$sc < \frac{\beta}{1-\beta} \frac{[\overline{r} - r_{00}]}{u_{00}^u} = sc^{p*}(say).$$
 (4.33)

Source of Coordination Failure

It follows from (3.29) and (??) that for a range of schooling costs, $sc^{n*} < sc < sc^{p*}$ it is socially beneficial to institute a job training programme but it is not privately incentive compatible. While undertaking a social cost benefit analysis of training, the planner internalizes the gain in skilled sector output and the loss of unskilled sector output, the saving of vacancy cost in each sector, the loss of employed worker's leisure time as well as the search frictions. In a market economy, firms and workers do not internalize all these benefits and costs in the same way the social planner does. For example, an unskilled worker does not fully internalize the saving of a skilled firm's cost of keeping positions vacant while deciding about joining a skill centre. Likewise, a vacant firm will not pay attention to a worker's loss of leisure time if they train unskilled workers. This conflict of interest is at the very root of the cordination failure in training. There is underinvestment in training which is not socially optimal. ⁸

4.1 Redistributive Effects of Training

The social planning problem provides an important lesson that some one should pay for training for a range of schooling cost? Who should pay for training? The answer is not obvious because who bears the cost of training has redistributive effects on the values of firms and workers. The next proposition makes it clear.

Proposition 3 $J^{s}(1,0) < J^{s}(0,1), V^{s}(1,0) < V^{s}(0,1), E^{s}(1,0) > E^{s}(0,1), E^{s}(1,0) > E^{s}(0,1).$

Proof. Appendix.

When firms pay for training, skilled wages are higher than a scenario when workers pay for training for reasons mentioned in Lemma ??). The steady state values of both vacant and engaged skilled firms thus go down. Skilled workers, on the other hand, experience a higher wage and thus enjoy a gain in steady state value. Since the unskilled sector disappears, overall effect is that firms lose (gain) and workers gain (lose) when firms (workers) invest in training.

The aggregate welfare effects of training should take into account this redistributive effects of welfare. In the next section we turn to a calibration of our model to quantify the welfare effect of

⁸There is another possibility of overinvestment in training when it is socially undesirable to institute a job training programme but the private sector incurs this cost anyway. This happens when $sc^{p*} < sc < sc^{n*}$. In our calibrated model that we report next these cases are ruled out. We find that $sc^{p*} > sc^{n*}$.

instituting training in the economy.

5 Quantitative Analysis

In this section, we report a quantitative estimate of the welfare loss due to private underinvestment in training. There are two steps of this exercise. First, based on the available studies and model steady state properties, we compute the baseline estimates for our structural parameters of the model. Second, based on these baseline parameter values, we compute the schooling cost thresholds for the social planner and the private sector, namely sc^{p*} , sc^{f*} , sc^{w*} which are required to compute the welfare loss of underinvestment.

5.1 Fixing parameter values

There are 12 structural parameters, namely $\mu_0^{ws}, \mu_0^{fs}, p^s, p^u, b, c, \beta, \lambda^s, \lambda^u, \sigma^s, \sigma^u, \theta$ characterizing the economy. Because of the stylized nature of the model, it is dificult to find estimates from existing studies for all these 12 parameters for the UK economy within a common timeframe. Since we are calibrating the steady state properties of the model, we take the liberty of choosing available estimates for different time periods under the assumption that the UK economy is in a steady state equilibrium. We also assume that the steady state properties of the UK economy are similar to advanced OECD countries which justifes the selection of OECD estimates for a few model parameters in the absence of any suitable UK estimate.

The estimate of β is 0.99 as in Shimmer (2005). We assume that the job separation rates in skilled and unskilled sector are the same and set it at 0.1 as in Shimmer.

As there are four steady states in the model, (0,0), (0,1), (1,0), (1,1), the issue arises which steady state should be used for baseline calibration. Since the goal of the paper is to understand the reasons for the failure of job training, the relevant baseline steady state is chosen to be (0,0) which is the state of no training.

According to Nickell and Bell (1994), for UK the proportion of labour force in the skilled sector is 36.8% and in the unskilled sector, it is 28.2%. The remaining labour force is called nonemployment which includes discouraged unskilled workers. Since in our model we only have skilled and unskilled workers in the labour force, we normalize Nickell and Bell estimates to arrive at the proportion of skilled and unskilled workers in the labour force. This means that $\mu_0^{ws} = 36.8\%/(36.8\%+28.2\%)$ and

 $\mu_0^{wu} = 1 - \mu_0^{ws}.$

The unemployment benefit parameter b is proxied by the value of leisure time taken from Shimer (2005) and is fixed at 0.4. Using the same study, we fix the cost of vacancy, c and the bargaining parameter, θ at 0.21 and 0.71 respectively. Accomoglu and Zilibotti (2000) compute the value added per worker in low, medium and high skilled sectors in rich and poor countries. The ratio of the value added per worker in high to low skilled sectors is about 2.12 for both rich and poor countries. Based on their study p^s/p^u is thus fixed at 2.12.

The remaining parameters are μ_0^{sf} , μ_0^{uf} , λ^{ss} , λ^{uu} , λ^{us} are calculated using the steady state properties of the model. Without any loss of generality, for the purpose of calibration we assume that $\lambda^{us} = \lambda^{uu}$ which means that the probability of an unskilled worker meeting a skilled vacant firm is the same as the probability of an unskilled worker meeting an unskilled firm.

We need four steady equations to solve for μ_0^{sf} , μ_0^{uf} , λ^{ss} , λ^{uu} . The labour market clearing conditions in the skilled and unskilled sectors (Lemma 2) imply that ,

$$\mu_0^{iw} - u_{00}^i = \mu_0^{if} - v_{00}^i, \ i = u, s \tag{5.34}$$

From Lemma (2) we get:

$$\lambda^{ii} = \sigma^{i} \frac{\mu^{iw} - u^{i}_{00}}{\left[u^{i}_{00}\right]^{2} - \delta^{i} u^{i}_{00}}, i = u, s$$
(5.35)

If we have estimates of the unemployment and vacancy rates u_{00}^s , u_{00}^u , v_{00}^s , v_{00}^u our four equations spelled out in (5.34) and (5.35) can be solved for μ_0^{sf} , μ_0^{uf} , λ^{ss} , λ^{uu} . Estimates of u_{00}^s , u_{00}^u came from Nickell and Bell (1994). They estimate these unemployment rates for two levels of education, low education and high education as discussed earlier for two years 1973 and 1991. We use their estimates for the relatively recent year 1991 and normalize these by the proportion of workers in the labour force in each group to arrive at our estimates of u_{00}^s and u_{00}^u . Doing so, we obtain, $u_{00}^s = 8.92\%$ and $u_{00}^u = 24.15\%$.

Regarding the calibration of vacancy rates v_{00}^s, v_{00}^u , observe from the market clearing condition (5.34) that

$$u_{00}^s + u_{00}^u = v_{00}^s + v_{00}^u \tag{5.36}$$

Our calibrated vacancy rates must respect this vacancy-unemployment identity (5.36). To this

end, we use the Office of National Statistics (ONS) database to get some prior estimates of v_{00}^s , v_{00}^u . We call these estimates $v_{00}^{s,ONS}$ and $v_{00}^{u,ONS}$. ONS provides the vacancies per 100 jobs for 19 occupations. We select 9 of these occupations as skilled. The remaining occupations are classified as unskilled. ⁹ Evidently this classification of occupations among skilled and unskilled is a bit arbitrary. Our motivation for this classification is to remain consistent with the classification of Nicole and Bell among low and high education workers. We basically work on the assumption that 9 jobs selected as skilled require some form of formal education.

Using these ONS priors, we calculate v_{00}^s, v_{00}^u as follows:

$$\begin{aligned} v_{00}^{s} &= \frac{v_{00}^{s,ONS}}{v_{00}^{s,ONS} + v_{00}^{u,ONS}} (u_{00}^{s} + u_{00}^{u}) \\ v_{00}^{u} &= \frac{v_{00}^{u,ONS}}{v_{00}^{s,ONS} + v_{00}^{u,ONS}} (u_{00}^{s} + u_{00}^{u}) \end{aligned}$$

These estimates for vacancy rates are model consistent and satisfy the identity (5.36). Table 1 summarizes the baseline parameter values.

[Insert Table 1]

5.2 Welfare Effects of Training and Policy Implications

How does investment or lack of investment in training impact the welfare of workers and firms? For the no training state 00, the welfare for workers (W^w) is the sum of the values of skilled and unskilled workers. Likewise, the welfare of all firms (W^f) is the sum total of the values of the skilled and unskilled forms. In other words,

$$W_{\pi}^{w} = \sum_{i=s,u} (\mu_{\pi}^{iw} - u_{\pi}^{i})E^{i} + U^{i}u_{\pi}^{i}$$
(5.37)

⁹Skilled occupations are namely, (i) Real Estate Activities, (ii) Professional, Scientific & Technical, (iii) Admin & Support Service Activities, (iv) Public Administration & Defence, (v) Education, (vi) Human Health & Social Work, (vii) Arts, Entertainment & Recreation, (viii) Information and communication, (ix) Finance and Insurance. Unkilled occupations are: (i) mining and quarrying, (ii) manufacturing, (iii) Electricity and gas supply, (iv) water supply and sewage, (v) construction, (vi) wholesale and retail, (viii) transportation and storage, (ix) accommodation, (x) other services (xi) total services. The last two categories are unspecified occupations. Including these last two in the skilled category does not change the result significantly.

$$W_{\pi}^{f} = \sum_{i=s,u} \left[(\mu_{\pi}^{if} - v_{\pi}^{i})J^{i} + V^{i}v_{\pi}^{i} \right]$$
(5.38)

The welfare effect of training depends on who invests in training. In our model training can be imparted to workers by either the vacant skilled firms or unskilled workers themselves. In both cases, training has spillover effects on the values of all other firms and workers in the economy. We calculate the values of firms and workers by setting the schooling cost exactly equal to the corresponding training cost threshold. For example, when firm invests in training we set $sc = sc_f^{n*}$ at which a vacant skilled firm is just indifferent between training or no training. Likewise, when wokers invest in training, we set $sc = sc_w^{n*}$.

We next turn to the details of the calculations of the welfare effects of training. The training decision of either firm or worker has spillover effect on the values of all other firms and workers in the economy through strategic interdependence and impacts the aggregate welfare of all workers and firms as spelled out in (5.37) and (5.38).

Tables 3 and 4 summarize the changes in welfare of firms and workers and report the sensitivity analysis when crucial policy parameters (such as p^s/p^u or b) change. When a vacant skilled firm alone invests in training, by construction it has no effect on $V^s(1,0)$ when $sc = sc_f^{n*}$. However, it adversely impacts the value of occupied skilled firms J^s because skilled workers bargain a higher wage in proportion to the schooling cost incurred by the skilled firm ((see (??))). The overall effect on workers' and firms' welfare is positive. Firms lose by about 21 % and workers gain by 23%. The welfare of the whole economy (denoted as $W_{\pi}^e = W_{\pi}^w + W_{\pi}^f$) consisting of all workers and firms increases by 3.4%.

When unskilled worker alone invests in training, it has a different redistributive effect on the welfare of skilled and unskilled firms and workers. Since the schooling cost is now borne by the unskilled workers, both vacant and engaged skilled firms gain in value (Table 2). However, both unemployed and employed skilled workers lose because their bargained wage is less than a scenario where firms alone invest in training. Recall from (??) that the skilled workers can earn a higher wage only when firms bear the sunk cost of training. Since the skilled wage remains the same but unskilled workers end up paying a schooling cost, the value of unemployed unskilled workers U^s declines. Since E^s and U^s are positively related through the interlocking value functions (3.16) and (3.17), value of employed skilled workers also fall. Unskilled firms suffer loss because all unskilled workers turn skilled and leave the industry (Table 2). Overall, workers gain by 3.3% while all firms together gain by 10%. The whole economy gains in welfare by 7%.¹⁰

[Insert Table 2]

We next turn to calculation of welfare gain from training in our command economy. Recall from the analysis of the social planning problem that the planner is indifferent who undertakes the training programme. When there is no training forever, the social welfare (i.e W_{00}^s) from the social planner's viewpoint is given by $r_{00}/(1-\beta)$. Starting from a no training state if the planner initiates a training programme, the social welfare (i.e $W_{\pi}^s, \pi \neq 0$) is given by $r_{00} + (\beta/(1-\beta)\bar{r})$. Thus the proportional change in the social welfare due to institution of training is given by:

$$\frac{W_{\pi}^{s} - W_{00}^{s}}{W_{00}^{s}} = \frac{\beta \left(\overline{r} - r_{00}\right)}{r_{00}} = \left(1 - \beta\right) \frac{sc^{p*}u_{00}^{u}}{r_{00}}$$

The last columns of Tables and 4 report this change in social welfare. Since the social planner internalizes all the private costs and benefits, not surprisingly the welfare gain from the institution of a job programme is always higher in a planned economy than in a decentralized economy. Comparison of the last two columns of Table 3 and 4 reveals that when workers undertake a self financed training programme, the welfare gain in a decentralized economy comes close to the gain that one observes in a planned economy. For example, in the baseline case, the welfare gain from training is 7% when workers invest in training and welfare gain is 3% when firms invest in training. In a command economy the welfare is gain is 8% after institution of a training programme. On the other hand, the discrepancy between private and social welfare gains is much higher when firms impart training to workers. This discrepancy between private and social welfare gain is a measure of efficiency loss in a decentralized economy due to the coordination failure. It is also noticeable from Table 4 that this efficiency loss is higher in economies with a greater unemployment benefit. For example, when the benefit (b) is 0.4 and the worker initiates a self financed training, this efficiency loss is about 0.92%, while the same loss increases to 3.9% if the benefit is raised to 0.5.

A change in p^s/p^u raises the welfare gain in a private economy when either the firm or worker adopts training. The gain is higher when the firm initiates training. For example, an increase in

¹⁰The overall change in welfare is less than 10% because aggregate welfare is the weighted sum of workers' and firms' welfare. These weights change with respect to the state of training. These weight are also quite sensitivie to training because due to training all unskilled workers turn skilled.

 p^s/p^u from its baseline 2.12 to 2.5 raises the private welfare from 3% to 9% when firms undertake training. The efficiency loss due to coordination failure (the difference between the last two columns) also declines from 4.9% to 3.9%.

The upshot of this welfare analysis is that the welfare gain is the maximum if workers are given incentive to initiate training. This happens because the threshold training cost sc_f^* is lower for the firms than the workers sc_w^* (see Tables 3 and 4). Since the unskilled worker's decision to train affects the skilled wage, they are more willing to self-train. This is reflected in a relatively higher threshold training cost sc_w^* for workers. The policy implication is that providing training subsidy directly to workers or cutting back unemployment benefits which increases the opportunity cost of leisure can induce workers to undertake training. Providing subsidy to skilled firms (that raises p^s/p^u) can also help as it results in an overall welfare gain.

[Insert Table 4]

Skill Premium and Income Inequality 5.3

In our model, the skill premium (defined as the ratio skilled to unskilled wages, w_{00}^s/w_{00}^u) as shown in Tables 5 and 6 is about 50% in a state of no voluntary training programme for the baseline parameter values. This is of the same order of magnitude reported by Felstead et al. (2002) and Nickel and Bell (1994) A higher skilled:unskilled productivity gap (higher p^s/p^u) raises the skill premium because the skilled wage increases more than unskilled wages to reflect this productivity difference. On the other hand, a more liberal unemployment benefit (b) lowers the skill premium as evident from $(??)^{11}$. Since in our stylized model everyone becomes skilled following a job training, trivially the skill premium disappears after training.

Tables 7 and 8 compare the Gini How does a job training impact the income inequality? coefficient for economies with no training and positive training. Before the job training, the inequality is measured across four groups of workers, skilled and unskilled employed earning wages w_{00}^s and w_{00}^u respectively, skilled and unskilled unemployed collecting unemployment benefits b where $b < w_{00}^u < w_{00}^u$ A job training programme eliminates unskilled workers. The Gini coefficient in a state of w_{00}^{s} . no training is about 0.38, which is similar to the the gini cofficient reported by National Statistics (between 0.36 to 0.34).¹² . A job training increases this income inequality by 5 to 15% depending on

¹¹It is easy to verify that $\frac{\partial (w_{00}^s/w_{00}^u)}{\partial b} < 0$ if $p^s > p^u$. ¹²See http://www.statistics.gov.uk/cci/nugget.asp?id=332

who pays for training. Increase in inequality is more if firms invest in training rather than workers. This happens because the wage increase is more when firms invest in training for the reasons described earlier. Changes in productivity ratio and benefits have minor effects on the Lorenz ratio. Figure 1 plots the Lorenz curves for the two states of training setting the parameters at the baseline levels.

[Insert Table 5][Insert Table 6][Insert Table 7][Insert Table 8][Insert Figure 1]

6 Conclusion

In this paper, we attempt to explain two apparently conflicting stylized facts in the UK labour market. First, there is an acute skill shortage in the UK economy. High skilled positions remain vacant for a long time while there is an excess supply of intermediate skills. Second, there exists a substantial high to low skill premium. There is an unexploited profit opportunity in the high skilled sector while neither the worker nor the firm appears to take advantage of these through job training. We propose an explanation of this anomaly in terms of a coordination failure of firm's and worker's decisions regarding job training. Our model demonstrates that while it is socially optimal to invest in job training, the private sector may not internalize this benefit. As a result, there could be voluntary underinvestment in training.

The quantitative analysis based on a calibrated version of our model suggests that a job training programme can increase the societal welfare by 7 to 9%. The welfare gain is higher if instead of firms, workers bear the cost of training. In a state of no training, a skill premium of the order of 50% can arise which can be eliminated by instituting a training programme. A voluntary underinvestment in training thus reflects a state of social inefficiency which a benevolent government can correct by a public policy package such as output subsidy to skilled firms and less liberal unemployment benefits. The income inequality can, however, increase by nearly 15% once a training programme is in place.

Appendix 1:

Proof of Lemma. 1: Solve μ^{uw} and μ^{uf} . Using (2.6) and (2.7) we get:

$$\Delta \mu^{sw} = \xi_t^w u_t^u + \xi_t^f \lambda^{us} u_t^u v_t^s, \tag{A.1}$$

$$\Delta \mu^{sf} = 0 \tag{A.2}$$

If $\left(\xi_t^f, \xi_t^w\right) \neq (0, 0)$, conjecture a solution $\mu^{uw} = 0$. Since $0 \le u^u \le \mu^{uw}$ this means $u^u = 0$ as well ¹³. Also $\mu^{sf} = \mu_0^{sf} = 1 - \mu^{uf}$.

The steady state solutions using (2.5) and (2.3) using the previous solutions we have:

$$\sigma^{u}(\mu^{uw} - u^{u}) = \lambda^{uu}u^{u}v^{u} + \lambda^{us}u^{u}v^{s}$$
(A.3)

$$\sigma^{u}(\mu^{uf} - v^{u}) = \lambda^{uu} u^{u} v^{u}$$
(A.4)

implying $v^u = \mu_0^{uf}$. The other solutions satisfies the (A.3) and (A.4) as well.

Plugging in $u^u = 0$ in equation (2.2) and (2.4) we solve for u^s and v^s from as:

$$\sigma^s(\mu^{sw} - u^s) = \lambda^{ss} u^s v^s \tag{A.5}$$

$$\sigma^s(\mu^{sf} - v^s) = \lambda^{ss} u^s v^s \tag{A.6}$$

 $(\mu^{sw} - u^s) = (\mu^{sf} - v^s)$ or $v^s = u^s - (\mu^{sw} - \mu^{sf}) = u^s - \delta^s$, where $\delta^s = (\mu^{sw} - \mu^{sf})$ is the equilibrium mismatch between skilled workers and skilled firms. Use (A.5) and (A.6) to get:

$$\sigma^{s}(\mu^{sw} - u^{s}) - \lambda^{ss}u^{s}[u^{s} - \delta^{s}] = 0$$
$$u^{s}[u^{s} - \delta^{s}] - \eta^{ss}(\mu^{sw} - u^{s}) = 0$$
$$[u^{s}]^{2} - (\delta^{s} - \eta^{ss})u^{s} - \eta^{ss}\mu^{sw} = 0$$

¹³There is another solution which is $u^u = u_0^u = 0$ and $\mu^{sw} = \mu_0^{sw}$ satisfying (2.6). This is unstable since if u_0^u is purturbed away from zero μ^{sw} fails to converge to μ_0^{uw} , infact it converges to one.

where $\eta^{ss} = \frac{\sigma^s}{\lambda^{ss}}$. Then solving the quadratic system we have

$$u^{s} = \frac{1}{2} \left(\left[\delta^{s} - \eta^{ss} \right] + \sqrt{\left[\delta^{s}_{0} - \eta^{s} \right]^{2} + 4\eta^{ss} \mu^{sw}} \right)$$
$$v^{s} = u^{s} - \delta^{s}$$

Plugging in the values of $\mu^{sw} = 1$ and $\mu^{sf} = \mu_0^{sf}$ i.e. $\delta^s = \left(1 - \mu_0^{sf}\right) = \mu_0^{uf}$ we have

$$u^{s} = \frac{1}{2} \left(\left[\mu_{0}^{uf} - \eta^{s} \right] + \sqrt{\left[\mu_{0}^{uf} - \eta^{ss} \right]^{2} + 4\eta^{ss}} \right)$$
$$v^{s} = u^{s} - \mu_{0}^{uf}.$$

Proof of Lemma. 2: Using 2.7 and 2.6 $\mu^{s,f} = \mu_0^{s,f}$ and $\mu^{s,w} = \mu_0^{sw}$ do not change and are given by initial conditions.

Using 2.4 and 2.2 we have $(\mu_0^{hw} - u^h) = (\mu_0^{hf} - v^h)$ or $v^h = u^h - (\mu_0^{hw} - \mu_0^{hf}) = u^h - \delta_0^h$, where δ_0^h is the initial mismatch between skilled workers and skilled firms. We can then solve for u^s from equation 2.5 and 2.3, (or 2.4 and 2.2) as before

$$\begin{aligned} u^{h} &= \frac{1}{2} \left(\left[\delta^{h}_{0} - \eta^{hh} \right] + \sqrt{\left[\delta^{h}_{0} - \eta^{hh} \right]^{2} + 4 \eta^{hh} \mu^{hw}_{0}} \right) \\ v^{h} &= u^{h} - \delta^{h}_{0} = v^{h}_{10}. \end{aligned}$$

QED.

Proof of Corollary. 1: Define function

$$u(\mu^{w}) = \frac{1}{2} \left(\left[\mu^{w} - \mu_{0}^{sf} - \eta \right] + \sqrt{\left[\mu^{w} - \mu_{0}^{sf} - \eta \right]^{2} + 4\eta^{ss}\mu^{w}} \right).$$

Note that $u(\mu_0^{sw}) = u_{00}^s$, $u(1) = \overline{u}^s$, and $u(\mu^w) \ge 0$ for $0 \le \mu^w \le 1$. Differentiate $u(\mu^w)$ w.r.t. μ^w

and obtain

$$\begin{aligned} \frac{\partial u\left(\mu^{w}\right)}{\partial \mu^{w}} &= \frac{1}{2} \left(1 + \frac{1}{2} \frac{2\left[\mu^{w} - \mu_{0}^{sf} - \eta\right] + 4\eta^{ss}}{\sqrt{\left[\mu^{w} - \mu_{0}^{sf} - \eta\right]^{2} + 4\eta^{ss}\mu^{w}}} \right) \\ &= \frac{\frac{1}{2} \sqrt{\left[\mu^{w} - \mu_{0}^{sf} - \eta\right]^{2} + 4\eta^{ss}\mu^{w}} + \frac{1}{2} \left(\mu^{w} - \mu_{0}^{sf}\right) + \eta^{ss}}{\sqrt{\left[\mu^{w} - \mu_{0}^{sf} - \eta\right]^{2} + 4\eta^{ss}\mu^{w}}} \\ &= \frac{u\left(\mu^{w}\right) + \eta^{ss}}{\sqrt{\left[\mu^{w} - \mu_{0}^{sf} - \eta\right]^{2} + 4\eta^{ss}\mu^{w}}} \ge 0 \end{aligned}$$

Therefore $\overline{u}^{s} = u(1) \ge u(\mu_{0}^{sw}) = u_{00}^{s}$.

Appendix 2:

.1 Derivation of Nash Bargaining Wages

To avoid solving very similar equaltions for the value functions The following lemma is needed for the derivation of the value functions, Nash bargaining wages and the derivation of threshold schooling costs.

Lemma 5 : Define a set of equations in J, V, E, U and ω with parameters $\beta, \theta, p, c_{\pi}, b, \lambda u, \lambda v$ and σ as

$$J = p - \omega + \beta [(1 - \sigma)J + \sigma V]$$

$$V = -c_{\pi} + \beta [\lambda u J + (1 - \lambda u) V]$$

$$E = \omega + \beta [\sigma U + (1 - \sigma)E]$$

$$U = b + \beta [\lambda v E + (1 - \lambda v)U]$$

$$\omega = \arg \max_{\omega} \theta \log (J - V) + (1 - \theta) \log (E - U)$$

then the solutions are given by:

$$\begin{split} \omega &= (1-\theta) \, (p+c) + \theta b \\ J &= \frac{1}{(1-\beta)} \left[-c_{\pi} + \frac{(p+c_{\pi}-b) \, \theta \, (1-\beta \, [1-\lambda u])}{(1-\beta \, [1-\sigma-\lambda u])} \right] \\ V &= \frac{1}{(1-\beta)} \left[-c_{\pi} + \frac{(p+c_{\pi}-b) \, \theta \beta \lambda u}{(1-\beta \, [1-\sigma-\lambda u])} \right] \\ E &= \frac{1}{(1-\beta)} \left[b + \frac{(p+c_{\pi}-b) \, (1-\theta) \, (1-\beta \, [1-\lambda v])}{(1-\beta \, [1-\sigma-\lambda v])} \right] \\ U &= \frac{1}{(1-\beta)} \left[b + \frac{(p+c_{\pi}-b) \, (1-\theta) \, \beta \lambda v}{(1-\beta \, [1-\sigma-\lambda v])} \right]. \end{split}$$

Proof of Lemma. 5: Note that

$$(1 - \beta) J = p - \omega - \beta \sigma [J - V]$$

$$(1 - \beta) V = -c_{\pi} + \beta \lambda u [J - V]$$

$$(1 - \beta) E = \omega - \beta \sigma [E - U]$$

$$(1 - \beta) U = b + \beta \lambda v [E - U]$$

then

$$J = \frac{p - \omega}{(1 - \beta)} - \frac{\beta \sigma}{(1 - \beta)} [J - V]$$

$$V = \frac{-c_{\pi}}{(1 - \beta)} + \frac{\beta \lambda u}{(1 - \beta)} [J - V]$$

$$E = \frac{\omega}{(1 - \beta)} - \frac{\beta \sigma}{(1 - \beta)} [E - U]$$

$$U = \frac{b}{(1 - \beta)} + \frac{\beta \lambda v}{(1 - \beta)} [E - U]$$
(A.7)

Differencing we get,

$$[J-V] = \frac{p-\omega+c_{\pi}}{(1-\beta)} - \frac{\beta(\sigma+\lambda u)}{(1-\beta)}[J-V]$$
$$[E-U] = \frac{\omega-b}{(1-\beta)} - \frac{\beta(\sigma+\lambda v)}{(1-\beta)}[E-U]$$

$$[J-V]\left(1+\frac{\beta\left(\sigma+\lambda u\right)}{\left(1-\beta\right)}\right) = \frac{p-\omega+c_{\pi}}{\left(1-\beta\right)}$$
$$[E-U]\left(1+\frac{\beta\left(\sigma+\lambda v\right)}{\left(1-\beta\right)}\right) = \frac{\omega-b}{\left(1-\beta\right)}$$

$$[J-V] = \frac{p-\omega+c_{\pi}}{(1-\beta [1-(\sigma+\lambda u)])}$$
$$[E-U] = \frac{\omega-b}{(1-\beta [1-(\sigma+\lambda v)])}$$

First order conditions from the wage equations give:

$$\frac{\theta}{p - \omega + c_{\pi}} = \frac{1 - \theta}{\omega - b}$$

$$\omega = (1 - \theta) (p + c_{\pi}) + \theta b$$
(A.8)

Replacing the value of ω we have,

$$[J-V] = \frac{\theta (p-b+c_{\pi})}{(1-\beta [1-(\sigma+\lambda u)])} \text{ and } [E-U] = \frac{(1-\theta) (p-b+c_{\pi})}{(1-\beta [1-(\sigma+\lambda v)])}$$

Therefore, inserting the value differences in (A.7) will give the result.

Skilled Sector wages:

Proof of lemma. 3: Rewrite the value functions (3.16), (3.17), (3.21), and (3.15) as before. Notice that from Lemma 5, the wages are independent of $\lambda u, \lambda v$ and σ . Therefore the wages in the skilled sector are given by the parameters $p = p^s$ and $c_{\pi} = (c + \xi^f sc_f)$. Hence

$$\omega^{s} = (1 - \theta) \left(p^{s} + c + \xi^{f} sc \right) + \theta b$$

Unskilled Sector wages:

The only relevant state for the unskilled sector is the state of no training, i.e $(\xi^f, \xi^w) = (0, 0)$. We rewrite (3.18), (3.14), (3.19) and (3.20) as:

$$E^{u} = \omega^{u} + \beta \left[\sigma^{u} U^{u} + (1 - \sigma^{u}) E^{u} \right]$$
(A.9)

$$U^{u}(0,0) = b - \beta \left[\lambda^{uu} v_{00}^{u} E^{u} + (1 - \lambda^{uu} v_{00}^{u}) U^{u}(0,0)\right]$$

$$J^{u} = p^{u} - \omega^{u} + \beta \left[\sigma^{u} V^{u} + (1 - \sigma^{u}) J^{u}\right]$$
(A.10)

$$V^{u} = -c + \beta \left[\lambda^{uu} u^{u}_{00} J^{u} + (1 - \lambda^{uu} u^{u}_{00}) V^{u} \right]$$
(A.11)

then using lemma 5 we have,

$$\omega^{u}(0,0) = (1-\theta)(p^{u}+c) + \theta b.$$

Skilled Sector Welfare:

Proof of Proposition. ??: Notice that in lemma 5 by plugging in the parameters $p = p^s, c_{\pi} = (c + \xi^f s c_f), b' = b, \sigma = \sigma^s, \lambda v = \lambda^{ss} \overline{v}^s$ and $\lambda u = \lambda^{ss} \overline{u}^s$ we get the equations in the skilled sector as (3.17), (3.16), (3.14), (3.18) and (3.22). We get the skilled sector values when any agent invest as

$$E^{s}\left(\xi^{f},\xi^{w}\right) = \frac{1}{(1-\beta)} \left[b + \frac{\left(p^{s} + c + \xi^{f}sc_{f} - b\right)\left(1 - \theta\right)\left(1 - \beta\left[1 - \lambda^{ss}\overline{v}^{s}\right]\right)}{\left(1 - \beta\left[1 - \sigma^{s} - \lambda^{ss}\overline{v}^{s}\right]\right)} \right]$$
(A.12)

$$U^{s}\left(\xi^{f},\xi^{w}\right) = \frac{1}{\left(1-\beta\right)}\left[b + \frac{\left(p+c+\xi^{f}sc_{f}-b\right)\left(1-\theta\right)\beta\lambda^{ss}\overline{v}^{s}}{\left(1-\beta\left[1-\sigma^{s}-\lambda^{ss}\overline{v}^{s}\right]\right)}\right]$$
(A.13)

$$J^{s}\left(\xi^{f},\xi^{w}\right) = \frac{1}{\left(1-\beta\right)}\left[-\left(c+\xi^{f}sc_{f}\right)+\frac{\left(p+c+\xi^{f}sc_{f}-b\right)\theta\left(1-\beta\left[1-\lambda^{ss}\overline{u}^{s}\right]\right)}{\left(1-\beta\left[1-\sigma^{s}-\lambda^{ss}\overline{u}^{s}\right]\right)}\right] \quad (A.14)$$

$$V^{s}\left(\xi^{f},\xi^{w}\right) = \frac{1}{(1-\beta)}\left[-\left(c+\xi^{f}sc_{f}\right) + \frac{\left(p+c+\xi^{f}sc_{f}-b\right)\theta\beta\lambda^{ss}\overline{u}^{s}}{\left(1-\beta\left[1-\sigma^{s}-\lambda^{ss}\overline{u}^{s}\right]\right)}\right]$$
(A.15)

therefore

$$E^{s}(1,0) - E^{s}(0,1) = \frac{sc_{f}}{(1-\beta)} \left[\frac{(1-\theta)(1-\beta[1-\lambda^{ss}\overline{v}^{s}])}{(1-\beta[1-\sigma^{s}-\lambda^{ss}\overline{v}^{s}])} \right] > 0$$
(A.16)

$$U^{s}(1,0) - U^{s}(0,1) = \frac{sc_{f}}{(1-\beta)} \left[\frac{(1-\theta)\,\beta\lambda^{ss}\overline{v}^{s}}{(1-\beta\,[1-\sigma^{s}-\lambda^{ss}\overline{v}^{s}])} \right] > 0 \tag{A.17}$$

$$J^{s}(1,0) - J^{s}(0,1) = \frac{sc_{f}}{(1-\beta)} \left[-1 + \frac{\theta \left(1 - \beta \left[1 - \lambda^{ss} \overline{u}^{s}\right]\right)}{\left(1 - \beta \left[1 - \sigma^{s} - \lambda^{ss} \overline{u}^{s}\right]\right)} \right] < 0$$
(A.18)

$$V^{s}(1,0) - V^{s}(0,1) = \frac{sc_{f}}{(1-\beta)} \left[-1 + \frac{\theta\beta\lambda^{ss}\overline{u}^{s}}{(1-\beta\left[1-\sigma^{s}-\lambda^{ss}\overline{u}^{s}\right])} \right] < 0$$
(A.19)

In the unskilled sector the only relevant agent is the vacant unskilled firm whose value is $V^s(1,0) = V^s(0,1) = -c$. Since in the state of training there are no unskilled workers are active

Derivation of threshold schooling costs

When $\left(\xi^f,\xi^w\right) = (0,0)$ from lemma 5 we get:

$$U^{u}(0,0) = \frac{b}{1-\beta} + \frac{\beta\lambda^{uu}v_{00}^{u}}{1-\beta} \frac{(1-\theta)(p^{u}+c-b)}{1-\beta[1-\sigma^{u}-\lambda^{uu}v_{00}^{u}]}$$
$$V^{s}(0,0) = -\frac{c}{1-\beta} + \frac{\beta\lambda^{ss}u_{00}^{s}}{1-\beta} \frac{\theta(p^{s}+c-b)}{1-\beta(1-\sigma^{s}-\lambda^{ss}u_{00}^{s})}.$$

When the firm invests, i.e. $(\xi^f, \xi^w) = (1, 0)$ from lemma 5 we get:

$$V^{s}(1,0) = -\frac{c+sc_{f}}{1-\beta} + \frac{\beta\lambda^{ss}\overline{u}^{s}}{1-\beta} \frac{\theta\left(p^{s}+c-b+sc_{f}\right)}{1-\beta\left(1-\sigma^{u}-\lambda^{ss}\overline{u}^{s}\right)}.$$
(A.20)

When the worker invests, i.e. $(\xi^f, \xi^w) = (0, 1)$ from lemma 5 and the previous equations we get:

$$U^{u}(0,1) = U^{s}(0,1) - sc_{w}.$$
(A.21)

We calculate the threshold Nash-equilibrium cost for the worker by equating $U^{u}(0,0) = U^{u}(0,1)$ respectively. Therefore

$$sc_w^{*n} = \frac{\beta\left(1-\theta\right)}{1-\beta} \left[\frac{\lambda^{ss}\overline{v}^s\left(p^s+c-b\right)}{1-\beta\left[1-\sigma^s-\lambda^{ss}\overline{v}^s\right]} - \frac{\lambda^{\mathrm{uu}}v_{00}^u\left(p^u+c-b\right)}{1-\beta\left[1-\sigma^u-\lambda^{\mathrm{uu}}v_{00}^u\right]} \right].$$

Obtain, Nash-equilibrium cost for the firm by equating and $V^{s}(0,0) = V^{s}(1,0)$, this implies,

$$-sc_{f}^{*n} + \frac{\theta\left(p^{s}+c-b+sc_{f}^{*n}\right)\beta\lambda^{ss}\overline{u}^{s}}{1-\beta\left(1-\sigma^{u}-\lambda^{ss}\overline{u}^{s}\right)} = \frac{\theta\left(p^{s}+c-b\right)\beta\lambda^{ss}u_{00}^{s}}{1-\beta\left(1-\sigma^{s}-\lambda^{ss}u_{00}^{s}\right)} \\ \left[\frac{\theta\beta\lambda^{ss}\overline{u}^{s}}{1-\beta\left(1-\sigma^{u}-\lambda^{ss}\overline{u}^{s}\right)}-1\right]sc_{f}^{*n} = (p^{s}+c-b)\left(\frac{\beta\lambda^{ss}\theta u_{00}^{s}}{1-\beta\left(1-\sigma^{s}-\lambda^{ss}u_{00}^{s}\right)}-\frac{\beta\lambda^{ss}\theta\overline{u}^{s}}{1-\beta\left(1-\sigma^{u}-\lambda^{ss}\overline{u}^{s}\right)}\right)$$

therefore

$$sc_{f}^{*n} = (p^{s} + c - b) \frac{(\overline{\alpha} - \alpha_{00})}{(1 - \overline{\alpha})}, \text{ where}$$
$$\overline{\alpha} = \frac{\beta \lambda^{ss} \theta \overline{u}^{s}}{1 - \beta (1 - \sigma^{u} - \lambda^{ss} \overline{u}^{s})} \text{ and } \alpha_{00} = \frac{\beta \lambda^{ss} \theta u_{00}^{s}}{1 - \beta (1 - \sigma^{s} - \lambda^{ss} u_{00}^{s})}$$
